t [ps]

CREM trajectories: N = 100; valid = 100

Full CREM calibration; secular $P(a) \propto a^{-4}$

cutoff: $r = 0.01 a_0$; all orbits start at $r = a_0$

$\langle t_{\text{collapse}} \rangle = 3.0201 \pm 0.1385$ ps (SE of mean)

sample $\sigma / \langle t \rangle = 0.45858$ (narrow, NOT exponential)

blue dashed: descriptive $\exp()$ through t - shape

is illustrative only, the sample is not exponential.

External comparison only:

$\tau_{\text{exp}} = 125.14 \pm 0.026623$ ps ($\tau_{\text{exp}} / \langle t \rangle \approx 41.4$)

p-Ps and o-Ps share this classical inspiral: they differ

only by initial dipole alignment ($\approx 10^{-5}$ of Coulomb),

while τ_{exp} differs by $\approx 10^3$. Scale reference,

not a prediction of the annihilation lifetime.

Al-Ramadhan & Gidley, PRL 72 (1994)
