

CREM calibration diagnostics

trajectories: 100; valid collapse extrapolations: 100

calibration outcome reached-cutoff / observation-limit / failed = 0 / 100 / 0

reached-cutoff entries use the integrated time directly;

observation-limit entries use the secular extrapolation.

The photon panels opposite are EXACT reference curves, not samples.

The annihilation generator is a quantum prescription independent of the classical model; sampling it here would only have reproduced the distribution it draws from. Its self-consistency (energy, momentum, mass-shell and parent-invariant closure, isotropy, Ore-Powell shape) is checked in `positronium_validation`, where a unit test belongs.
